

**Academic Year: 2022-23**

**Semester: IV**

**Class / Branch: SE IT**

**Subject: Python Lab**

---

## **Experiment No. 07**

**Aim:** Write python programs to understand creation of a menu driven application which should cover all the built-in exceptions in python

**Software used:- Python2.7.12**

### **Theory :-**

What is Exception?

An exception is an event, which occurs during the execution of a program that disrupts the normal flow of the program's instructions. In general, when a Python script encounters a situation that it cannot cope with, it raises an exception. An exception is a Python object that represents an error.

When a Python script raises an exception, it must either handle the exception immediately otherwise it terminates and quits.

### **Handling an exception**

If you have some *suspicious* code that may raise an exception, you can defend your program by placing the suspicious code in a **try:** block. After the try: block, include an **except:** statement, followed by a block of code which handles the problem as elegantly as possible.

### **Syntax**

Here is simple syntax of *try....except...else* blocks –

try:

    You do your operations here;

    .....

except *ExceptionI*:

    If there is ExceptionI, then execute this block.

`except ExceptionII:`

    If there is *ExceptionII*, then execute this block.

    .....

`else:`

    If there is no exception then execute this block.

## User-Defined Exceptions

Python also allows you to create your own exceptions by deriving classes from the standard built-in exceptions.

Here is an example related to *RuntimeError*. Here, a class is created that is subclassed from *RuntimeError*. This is useful when you need to display more specific information when an exception is caught.

In the try block, the user-defined exception is raised and caught in the except block. The variable *e* is used to create an instance of the class *Networkerror*.

```
class Networkerror(RuntimeError):  
    def __init__(self, arg):  
        self.args = arg
```

So once you defined above class, you can raise the exception as follows –

```
try:  
    raise Networkerror("Bad hostname")  
except Networkerror,e:  
    print e.args
```

**Conclusion :-** Thus we have studied exception handling in python to deal with runtime or unexpected errors. Exceptions can be handled using assertions or built-in functions provided by Python.
